Sorting is not easy

An N-element permutation is an N-element sequence of distinct numbers from the set $\{1, 2, ..., n\}$. For example the sequence 2,1,4,5,3 is a 5-element permutation. P is an N-element permutation. Your task is to sort P in ascending order. But because it is very simple, I have a new rule for you. You have two sequences P and Q. P is an N-element permutation and Q is initially empty and formed by sorting P (i.e. finally Q = 1, 2, 3,..., N). You have to implement N steps to sort P. In the i-th step, P has N-i+1 remaining elements, Q has i-1 elements and you have to choose some x-th element (from the N-i+1 available elements) of P and put it to the left or to the right of Q. The cost of this step is equal to x * i. The total cost is the sum of costs of individual steps. After N steps, Q must be an ascending sequence. Your task is to minimize the total cost.

Input

The first line of the input file is T (T \leq 10), the number of test cases. Then descriptions of T test cases follow. The description of each test case consists of two lines. The first line contains a single integer N (1 \leq N \leq 1000). The second line contains N distinct integers from the set {1, 2, .., N}, the N-element permutation P.

Output

For each test case your program should write one line, containing a single integer - the minimum total cost of sorting.

Example

```
\begin{array}{l} N=4\\ P=\{4,1,3,2\}\\ Step\ 1,\ Choose\ 3\text{-rd},\ P=\{4,1,2\},\ Q=\{3\}\ ,\ Cost=3\\ Step\ 2,\ Choose\ 1\text{-st},\ P=\{1,2\},\ Q=\{3,4\}\ ,\ Cost=6\\ Step\ 3,\ Choose\ 2\text{-nd},\ P=\{1\},\ Q=\{2,3,4\}\ ,\ Cost=4\\ The\ total\ cost\ is\ 15.\\ Another\ way\ to\ sort:\\ Step\ 1,\ Choose\ 4\text{-th},\ P=\{4,1,3\},\ Q=\{2\}\ ,\ Cost=4\\ Step\ 2,\ Choose\ 2\text{-nd},\ P=\{4,3\},\ Q=\{1,2,3\}\ ,\ Cost=4\\ Step\ 3,\ Choose\ 2\text{-nd},\ P=\{4\},\ Q=\{1,2,3\}\ ,\ Cost=6\\ Step\ 4,\ Choose\ 1\text{-st},\ P=\{\},\ Q=\{1,2,3,4\},\ Cost=4\\ The\ total\ cost\ is\ 18.\\ \end{lnput:}
```

Output:

4132
